Intestinal Ischemia
Chronic Mesenteric Ischemia

Emori Bizer, M.D.
University of Louisville
Gastroenterology/Hepatology
March 27, 2008
Board Question:

An 80 year old woman with CAD complains to PCC that she has had abdominal pain for the past 4-6 months. Typically, it occurs 30 minutes postprandially and usually resolves in 1-3 hours. The severity of the pain has increased, and she is losing weight. Exam reveals a cachectic woman, but no abnormality is found on abdominal exam. The additional symptom that would be most suggestive of chronic mesenteric ischemia is:

a. Intermittent nausea and vomiting
b. Bloating
c. Fear of eating resulting in weight loss
d. Diarrhea
Intestinal Ischemia

- Objectives:
  - Review vascular anatomy of GI tract
  - Pathophysiology of intestinal ischemia
  - Review types of intestinal ischemia
  - Diagnosis of intestinal ischemia
  - Management of intestinal ischemia
  - Board-style questions
Who cares?

- MORTALITY
  - Acute Mesenteric Ischemia
    - Early diagnosis and intervention: 10%
    - Infarction: 60%-93%
  - Colon Ischemia: 50%
  - Mesenteric Venous Thrombosis: 20-50%

  "Occlusion of the mesenteric vessels is apt to be regarded as one of those conditions of which the diagnosis is impossible, the prognosis hopeless, and the treatment almost useless" (Cokkinis, 1926).
Intestinal Ischemia

- Spectrum of disorders
  - Acute vs. Chronic
  - Arterial vs. Venous disturbance
  - Small Intestine vs. Large Intestine vs. Both

- **Acute** is more common than Chronic
- **Arterial** disease is more common than Venous
### Types and Approximate Frequencies of Intestinal Ischemia

<table>

</tbody>
</table>

*Mesenteric venous thrombosis may manifest as colon ischemia, acute mesenteric ischemia, or as focal segmental ischemia. The frequency of mesenteric venous thrombosis is rising as computed tomography is performed more commonly.*
Celiac Axis

- 3 major branches: left gastric, common hepatic, and splenic arteries
- Provides arterial blood supply to:
  - STOMACH
  - DUODENUM
  - PANCREAS
  - LIVER

Figure 111-1 Diagram of typical celiac axis anatomy. A, aorta; AIPD, anterior inferior pancreaticoduodenal artery; ASPD, anterior superior pancreaticoduodenal artery; C, celiac axis; CP, caudal pancreatic artery; DP, dorsal pancreatic artery; GD, gastroduodenal artery; H, common hepatic artery; LG, left gastric artery; PIPD, posterior inferior pancreaticoduodenal artery; PM, pancreata magna; RGE, right gastroepiploic artery; S, splenic artery; SM, superior mesenteric artery; TP, transverse pancreatic artery. (From Nebesar RA, Kornblith PL, Pollard JJ, Michels NA: Celiac and Superior Mesenteric Arteries: A Correlation of Angiograms and Dissections. Boston, Little, Brown, 1969.)
Superior Mesenteric Artery

- 4 major branches: inferior pancreaticoduodenal, middle colic, right colic, and ileocolic arteries
- Series of jejunal and ileal branches
  - form ARCADES
  - From the terminal arcade, straight vessels enter the intestinal wall
- Supplies:
  - JEJUNUM AND ILEUM
  - RIGHT HALF OF LARGE BOWEL

Figure 111-2 Diagram of typical superior mesenteric artery anatomy. A, aorta; AIPD, anterior inferior pancreaticoduodenal artery; COL, colic branches; I, ileal branches; IC, ileocolic artery; JEJ, jejunal branches; MC, middle colic artery; PIPD, posterior inferior pancreaticoduodenal artery; RC, right colic artery; SM, superior mesenteric artery. (From Nebesar RA, Kornblith PL, Pollard JJ, Michels NA: Celiac and Superior Mesenteric Arteries: A Correlation of Angiograms and Dissections. Boston, Little, Brown, 1969.)
Inferior Mesenteric Artery

- Branches include left colic artery, multiple sigmoid branches, and terminates as the superior rectal artery
- Supplies:
  - LARGE INTESTINE FROM DISTAL TRANSVERSE COLON TO PROXIMAL RECTUM
- **The distal rectum is supplied by the internal iliac artery and its hypogastric artery branch**

Figure 111-3 Diagram of typical inferior mesenteric artery anatomy. AOR, arc of Riolan; ASC, ascending branch of the left colic artery; CA, central artery; DSC, descending branch of the left colic artery; IM, inferior mesenteric artery; LMC, left branch of middle colic artery; MA, marginal artery; MC, middle colic artery; RMC, right branch of middle colic artery; S1, S2, S3, sigmoid branches; SM, superior mesenteric artery; SR, superior rectal artery. (From Nebesar RA, Kornblith PL, Pollard JJ, Michels NA: Celiac and Superior Mesenteric Arteries: A Correlation of Angiograms and Dissections. Boston, Little, Brown, 1969.)
Intestinal Ischemia - Pathophysiology

- **Innate preventative measures**
  - **Collateral circulation** – particularly to stomach, duodenum, and rectum, so less likely to have ischemia to these organs
  - Splenic flexure and sigmoid colon have fewer collateral vessels, so higher risk for ischemia
  - **Compensatory mechanisms** – 1/5 mesenteric capillaries are open at a time.

- The bowel can tolerate a 75% reduction of mesenteric blood flow and oxygen consumption for 12 hours with no microscopic changes of ischemia.
Intestinal Ischemia - Pathophysiology

- Occlusive vs nonocclusive (NOMI)
- Reversible ischemia to transmural infarction and perforation
- Vascular occlusion $\rightarrow$ collaterals open distally initially
- Hours of ischemia $\rightarrow$ vasoconstriction which reduces collateral flow
  - Vasoconstriction is irreversible after a certain period of time
- Tissue hypoxia leads to bowel wall spasm which leads to gut emptying
- Mucosal sloughing leads to GI bleeding
  - Occlusive: Hemorrhagic infarction is final common pathway
- Disruption of the mucosal barrier becomes allows bacteria, toxins, and vasoactive substances to be released into the systemic circulation
Intestinal Ischemia - Pathophysiology

- Ischemic damage from hypoxia and reperfusion
  - Brief insult: more damage during reperfusion
  - Long insult: more damage from hypoxia

- Reperfusion injury due to reactive oxygen radicals
  - Oxygen radicals cause cell lysis and necrosis on reperfusion of ischemic tissue
  - Xanthine Dehydrogenase – enzyme in nucleic acid degrad.
    - Converted to Xanthine Oxidase in ischemia
  - Xanthine oxidase (XO) – source of oxygen radicals
Non-ischemic Tissue

- Nucleic acids
- Nucleic acid degradation products

**Allopurinol inhibits XO = decreased epithelial cell necrosis during reperfusion

Ischemic Tissue

- XDH → XO
- Reactive oxygen radicals

Reperfusion Injury
Intestinal Ischemia - Pathophysiology

- Role of Neutrophils
  - Source of reactive oxygen metabolites
  - In reperfusion, XO → increased production of leukotriene B4 and platelet-activating factor = neutrophil adherence and migration
  - Increased microvascular injury by neutrophils causing release of proteases which disrupt endothelial barrier and tight junctions
  - In vitro, XO inhibitors and agents that inhibit leukocyte adherence and migration protect organs against reperfusion injury. In vivo, agents must be given before ischemic insult
Board Question:

A 71 year old woman comes to the ER with severe nausea, vomiting, and diarrhea determined to be secondary to viral gastroenteritis. Her BP is 70/50 mmHg. She is given IVF. One day later, she returns to the ER complaining of sudden onset of crampy LLQ pain and passage of bloody diarrhea. Sigmoidoscopy findings indicate her symptoms are due to:

a. Recurrence of viral GE
b. Superimposed bacterial infection
c. Ulcerative proctitis
d. Colon ischemia
Types of Intestinal Ischemia

- **Acute Mesenteric Ischemia**
  - Arterial – thrombus, embolus (cardiac), nonocclusive
  - Mesenteric Venous Thrombosis
  - Focal Segmental Ischemia - Venous

- Colon Ischemia

- Chronic Mesenteric Ischemia

- Vasculitis and Angiopathy of Splanchnic Circulation
Acute Mesenteric Ischemia

- Insufficient blood flow to all or part of the small bowel and may involve the right half of the colon (SMA)
- **SMA** most often site of embolic AMI due to straighter take-off from Aorta

**Causes and Approximate Frequencies of Acute Mesenteric Ischemia**

<table>
<thead>

</tr>
</tbody>
</table>
Acute Mesenteric Ischemia

- **Thrombotic AMI**
  - Final cause of ischemia may be sudden drop in cardiac output or ruptured plaque
  - Often 2/3 vessels must be occluded for symptoms

- **Nonocclusive Mesenteric Ischemia**
  - “low flow state” – hypovolemia, cardiogenic or septic shock
  - Failure of autoregulation
  - No thrombus or embolus
  - Cocaine, digitalis, vasopressin can cause local vasoconstriction
Acute Mesenteric Ischemia

- Risk Factors:
  - ≥50 y/o: CHF, cardiac arrhythmia, recent MI, hypotension
  - Young: amphetamines, cocaine, triptans, phenylephrine, thrombophilic d/o

- Signs and Symptoms:
  - Early: Abdominal pain
  - Late: Abdominal distention
    - First sign of intestinal infarction
  - If rebound tenderness or guarding = think infarction
  - GI bleeding
  - Recurrent bacteremia s/p cardiopulmonary arrest (gut translocation of bacteria)
  - Critically ill patient: intolerance to tube feeds
  - Confusion (especially in elderly)
Acute Mesenteric Ischemia

- Abdominal pain:
  - Acute
  - SMAT: postprandial pain in the weeks to months preceding the acute onset of severe pain
    - Late complication of severe atherosclerotic disease when usually 2/3 vessels occluded.
  - SMAE: sudden, severe pain accompanied by rapid, forceful bowel evacuation
  - MVT: indolent
  - NOMI: no pain in 25%
Acute Mesenteric Ischemia

- Diagnosis:
  - Labs – nonspecific; late-stage
  - Plain films – normal 70%
    - Formless fixed loops of SB, ileus, “thumbprinting” or pneumatosis
  - CT – arterial occlusion or venous thrombosis, intramural gas or portal venous gas, focal lack of bowel wall enhancement (sens 64%, spec 92%)
  - Dopplers – limited in clinical value
    - Visualize proximal portion of vessel, occlusion nondiagnostic, variable blood flow through SMA
    - Spec 92%, sensitivity 70-89%

Ileus and fixed formless SB loop due to SMAE
Acute Mesenteric Ischemia

Diagnosis . . .

- CTA – sens 71-96% and a spec of 92-94%, rapid
- MRA – sens 100%, spec 91%, but time-consuming
- Laparoscopy – less helpful b/c serosa may look normal when mucosa necrotic and SMA flow decreases with incr pressure
- Laparotomy – use when angiography not available or if signs of peritonitis
- Mesenteric Angiography – diagnostic and therapeutic, gold standard
  - Sens: 90-100%, spec 100%
  - Drawbacks: delays surgery, difficult in critically ill
  - Decreased mortality
  - Only way to dx NOMI

Infarcted loop of bowel.
SMV thrombus.
SMA embolus, s/p embolectomy.
Acute Mesenteric Ischemia - Management

- **STAT surgical consult**
- **SMAE:**
  - Acute abdomen: Laparotomy, embolectomy and/or resection
    - Re-exploration often – may leave abdomen open.
  - No peritonitis: Angiography
    - “Road map” for revascularization
    - Papaverine infusion
      - Given through angio catheter directly into SMA
    - VASODILATOR: Relieves mesenteric vasoconstriction
- **SMAT:**
  - Emergency surgical revascularization
Acute Mesenteric Ischemia - Management

- NOMI:
  - Papaverine infusion into SMA
    - Decreased mortality in small case series
  - Broad spectrum antibiotics (no RCTs)
  - No anticoagulants for first 48 hours, except in MVT
Mesenteric Venous Thrombosis

- 10% of Acute Mesenteric Ischemia
- Risk Factors:
  - Hypercoagulable States
    - Estrogen – OCP, HRT, pregnancy
    - Malignancy
    - DVT – 60% MVT have h/o peripheral DVT
  - Portal Hypertension
  - Inflammatory States – diverticulitis, pancreatitis, peritonitis, IBD
  - Trauma
  - Decompression Sickness
Mesenteric Venous Thrombosis

- **Location, Location, Location**
  - Initial thrombus location varies with etiology
    - Cirrhosis, Neoplasm: Start proximal, extend peripherally
    - Hypercoag state: Start peripherally and extend proximally

- **Rare intestinal infarction**

- **Pathophysiology:**
  - Impaired venous drainage leads to congestion and cyanosis of bowel and thickened bowel wall with intramural hemorrhage

- **Clinical:** acute, subacute, or chronic. Abdominal pain, GI bleed.

- **Diagnosis:**
  - SB wall thickening, thumbprinting
  - CT – test of choice
  - Angiography
  - Laparotomy – serosanguinuous peritoneal fluid, blue-black bowel, thrombi
Mesenteric Venous Thrombosis

**Treatment**

- Asymptomatic – 3-6 mos anticoagulation or no therapy
- Peritoneal signs – laparotomy
  - Papaverine infusion if viable bowel
  - Thrombectomy if possible
  - Immediate heparinization for 7-10 days (improves survival)
- No peritoneal signs – 3-6 mos anticoagulation
- Lifelong anticoagulation if hypercoagulable state
- EGD for esophageal varices if chronic MVT
Focal Segmental Ischemia

- Ischemia to a short segment of small intestine
- Causes: Atheromatous emboli, strangulated hernia, immune complex disorders/vasculitis, blunt abdominal trauma, segmental venous thrombosis, radiation therapy, OCP’s.
- Clinical: acute abdomen or chronic enteritis with chronic SBO from stricture with intermittent abdominal pain and vomiting
- Xray:
  - “blind loop” syndrome – bacterial overgrowth of the dilated loop proximal to the SBO.
  - Smooth tapered stricture with abrupt change to normal mucosa
- Treatment: surgical resection of involved bowel
Types of Intestinal Ischemia

- Acute Mesenteric Ischemia
  - Arterial – thrombus, embolus, nonocclusive
  - Mesenteric Venous Thrombosis
  - Focal Segmental Ischemia - Venous

- Colon Ischemia
  - Chronic Mesenteric Ischemia
  - Vasculitis and Angiopathy of Splanchnic Circulation
Colon Ischemia

- The Most Common form of Intestinal Ischemia
- Causes: Vast and often idiopathic
  - Emboli
  - Hematologic d/o – vasculitis, hypercoagulable states
  - Infectious – E.coli 0157:H7, HBV, CMV, parasites
  - Surgical – includes colonoscopy; more often Aortic, Cardiac
  - Drugs, Drugs, Drugs – GoLYTELY among many
    - NSAIDs, PCN, saline laxatives, cocaine, estrogens, IFN-α, Lotronex
  - Shock, Trauma
  - Obstructing colon lesions
  - Pancreatitis
  - Strangulated Hernia
  - Long distance running
Colon Ischemia

- Causes and affected segments:
  - Systemic low-flow states = Right colon
  - Local nonocclusive ischemic injury – the watershed area = splenic flexure and rectosigmoid
  - Ligation of IMA – sigmoid colon
  - Atheromatous emboli - short segments of injury
  - Nonocclusive injury – longer portions of colon
- In most cases, no specific cause is identified
Figure 111-12 Schematic of patterns of colon ischemia showing the percentage of involvement of each pattern in a total of 250 cases.
Colon Ischemia

- Pathology
  - Varies with duration and severity of ischemia
  - Mild: mucosal and submucosal hemorrhage and edema +/- partial necrosis and mucosal ulceration
  - Moderate: chronic ulcerations, crypt abscesses, pseudopolyps (**MIMICKS IBD**)
  - Severe: MP replaced by fibrous tissue (stricture formation)
  - Very Severe: transmural infarction
Colon Ischemia

- Clinical
  - Sudden, cramping pain, can be mild intensity
  - LLQ
  - Urgent need to defecate
  - Hematochezia within 24 hours (small volume)
Colon Ischemia - Diagnosis

- Unprepped colonoscopy w/in 48 hrs if no signs of peritonitis
  - Do not overdistend the colon – can worsen ischemia
  - “Hemorrhagic nodules” = submucosal bleeding
    - “thumbprints” on barium enema study
  - “Colon single-stripe sign” – single erythematous line with ulceration oriented along longitudinal axis of colon. 75% sensitive.
    - Indicates milder dz than if circumferential ulcer
- Rectal sparing
- Segmental disease
- Mucosal gangrene
- More sensitive than barium enema
Colon Ischemia - Diagnosis

- No Mesenteric Angiography unless cannot distinguish btw CI and AMI (Right colon involvement or severity of pain) b/c colon blood flow returns to normal by the time of presentation

- If unclear CI vs AMI, first order air enema
  - Will show presence of submucosal edema and hemorrhage of CI
  - If no thumbprinting seen or only in the right colon, then order mesenteric angiography
Colon Ischemia: Differential Diagnosis at Endoscopy

Ischemia or Crohn’s?

Ischemia or Neoplasm?
Colon Ischemia - Management

- If no peritonitis, conservative
  - Bowel rest, IVF, ABx
  - Rectal tube prn colon distention
  - Monitor labs, x-rays
- Signs of infarction = to OR
  - Worsening abdominal tenderness or rebound, guarding, fever

PLC: protein-losing colopathy
Types of Intestinal Ischemia

- Acute Mesenteric Ischemia
  - Arterial – thrombus, embolus, nonocclusive
  - Mesenteric Venous Thrombosis
  - Focal Segmental Ischemia - Venous

- Colon Ischemia

- **Chronic Mesenteric Ischemia**

- Vasculitis and Angiopathy of Splanchnic Circulation
Chronic Mesenteric Ischemia

“Intestinal Angina”

Prevalence: less than 5% of intestinal ischemia

Risk factors:
- coronary or peripheral vascular disease
- 75% of pts with CMI have h/o smoking
Chronic Mesenteric Ischemia

Pathophysiology:

- Almost always caused by mesenteric atherosclerosis
- New Theory: Ischemia of the small bowel due to preferential blood supply to stomach upon food ingestion
- Old Theory: Limited blood supply to the small intestine during digestion
Chronic Mesenteric Ischemia

- **Symptoms:** ABDOMINAL PAIN & WEIGHT LOSS

- **Abdominal Pain:**
  - Starts within 30 minutes of food ingestion
  - Increases in severity
  - Resolves over 1-3 hours acutely
  - Progressively increases in severity over time and may become continuous, unassociated with food intake
    - **BAD SIGN = INFARCTION IMINENT**

- **Fear of eating, resulting in weight loss**
  - “sitophobia”
Chronic Mesenteric Ischemia

- Other Symptoms:
  - Nausea, bloating
  - Episodic diarrhea
  - Constipation
  - Malabsorption
Chronic Mesenteric Ischemia

Uncommon presentations:

- Antral ulcers that do not heal with PPI
- Gastroparesis (reversible with revascularization!!)
- Acute cholecystitis

University of Louisville
Chronic Mesenteric Ischemia

- Physical Exam:
  - Overall benign
  - Cachexia if significant weight loss
  - Abdomen is NON-TENDER even if having pain
    - Pain out of proportion to physical exam
  - Could have abdominal distention
  - Abdominal bruit may be present
Chronic Mesenteric Ischemia

**Diagnosis**
- No specific diagnostic test – dx of exclusion
- X-Ray and CT – normal or vascular calcifications
- Endoscopy – may have antral ulcers not assoc with H.pylori
- Barium – normal or motility d/o or malabsorption
- Gastric Emptying Test – may be delayed
- Provocative balloon tonometry – evaluates the physiological adequacy of intestinal blood flow
Chronic Mesenteric Ischemia

**Diagnosis**

- **Duplex USN** – elevated peak systolic velocity in SMA of 275 cm/sec and CA of 200 cm/sec suggests 70% stenosis of these vessels, but does not establish diagnosis of CMI.

- **MRA or mesenteric angiography** – show anatomic limitations of splanchnic blood flow but cannot diagnose intestinal ischemia.
  - **Angiography** – at least 2 of 3 splanchnic vessels should be severely stenosed or occluded.
Chronic Mesenteric Ischemia

- Surgical Revascularization vs PTMA (percutaneous transluminal mesenteric angioplasty)
  - Literature with varied criteria to define outcomes
  - Initial success at revascularization similar
  - Surgical approach – bypass grafts, aortic reimplantation of SMA, and endarterectomy
    - Improved duration of graft patency but increased perioperative mortality
  - PTMA with decreased perioperative mortality but increased recurrence of symptoms and stenosis. Stenting improves these outcomes.
- Management based on surgical risk
Chronic Mesenteric Ischemia: Management

Figure 111-19 Algorithm for the management of chronic mesenteric ischemia. Solid lines indicate accepted management plan; dashed line indicates alternative management plan. CTA, computed tomographic angiogram; MRA, magnetic resonance angiography. (From Brandt LJ, Boley SJ: AGA technical review on intestinal ischemia: American Gastrointestinal Association. Gastroenterology 118:954, 2000.)
Types of Intestinal Ischemia

- **Acute Mesenteric Ischemia**
  - Arterial – thrombus, embolus, nonocclusive
  - Mesenteric Venous Thrombosis
  - Focal Segmental Ischemia - Venous

- **Colon Ischemia**

- **Chronic Mesenteric Ischemia**

- **Vasculitis and Angiopathy of Splanchnic Circulation**
Vasculitis

- Many types
- Segmental ischemia
- Clinical symptoms similar to other causes of ischemia
  - Abdominal pain, fever, bloody diarrhea, intestinal obstruction
  - Ulceration and strictures common; perforation uncommon
- Pathophysiology:
  - Immune complex deposition in the vascular walls leads to complement activation, inflammatory reaction; then aneurysms form which can rupture. Vascular occlusion, thrombosis, and fibrosis ensue.
- Treatment: steroids, immunosuppressants
Intestinal Ischemia

- A very basic algorithm from the 2000 AGA technical review on intestinal ischemia for the diagnosis and treatment of intestinal ischemia...
