## INTRODUCTION

Spectral contrast effects (SCEs) are context effects that bias speech perception. They occur when the auditory system perceptually magnifies spectral differences between sounds:

recursor More likely to hear

Sentence (unmodified)

Sentence with  $/\epsilon$ -like (high  $F_1$ )
frequencies emphasized

Sentence with  $/\iota$ -like (low  $F_1$ )
frequencies emphasized  $/\epsilon$ -like (low  $F_1$ )
frequencies emphasized  $/\epsilon$ -like (low  $F_1$ )

These context effects were significantly smaller when precursor sentences were spoken by 200 different talkers compared to a single talker (Assgari & Stilp, 2015, JASA)

• The underlying mechanism was unclear because talker (gender) variability and acoustic (fundamental frequency (f0), F1) variability were confounded

We investigated whether f0 variability and/or F1 variability modulate the magnitude of spectral context effects in vowel categorization

#### METHODS

# Sentences

 Bandpass filter added + 5 dB spectral peaks to select TIMIT sentences in the low-F<sub>1</sub> (100-400 Hz) or high-F<sub>1</sub> (550-850 Hz) region

#### voweis

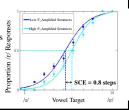

- Natural vowels interpolated from [1] to [ $\epsilon$ ] using PRAAT
- Same stimuli as used in Assgari & Stilp (2015)

#### Procedure

- · Trial structure: see schematic in Introduction
- Practice: 20 sentences from the AzBio corpus (Spahr et al., 2012 Ear Hear) paired with endpoint vowels; >80% accuracy needed to continue to test session
- Test: 2 or 4 blocks of 160 trials (each talker repeated 4 times per block)

## Analyses

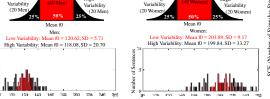

- SCE = # of stimulus steps between 50% points on Low-F1 and High-F1 response functions
- SCEs were calculated for each listener then averaged

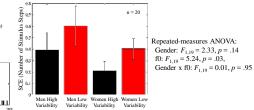

# ASSGARI, MOHIUDDIN, THEODORE & STILP, 2016, ASA

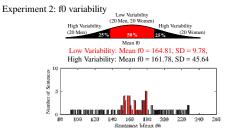

Motivation: Separating the individual contributions of f0 and gender variability to decreased spectral context effects

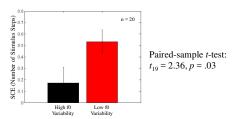

Experiment 1: Gender variability by f0 variability

Discussion: f0 variability modulated the magnitude of spectral context effects, but talker gender did not

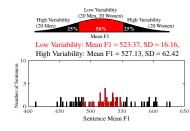

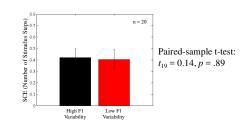

Discussion: High f0 variability decreases the magnitude of spectral context effects, even when talker gender is mixed

# **CURRENT STUDY**

Motivation: [1] and [ε] differ primarily on F1. Could F1 variability better explain the influence of acoustic variability on spectral context effects for these vowels? Sentences from Experiment 2 were rearranged into groups based on F1

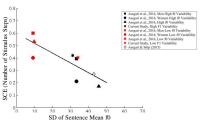

Discussion: F1 variability does not modulate the magnitude of spectral context effects in vowel categorization

## DISCUSSION

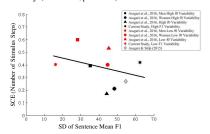

SCEs in vowel categorization are sensitive to variability in talker's mean f0, but not mean F1 or gender

- A strong negative relationship exists between SCE magnitude and f0 variability (r = -0.81, p < .01)</li>
- The current study sorted stimuli by F1, but results are what would be expected based on previous studies when considering f0 variability

Results parallel findings that f0 variability influenced talker normalization effects (Goldinger, 1996, *JEP:LMC*)

SCEs in vowel perception are not affected by mean F1 variability (r = -0.33, p = 0.37)

#### Future directions

In the current study, sentences were selected based on f0 and rearranged based on F1. This may not capture the full range of F1 variability.

- Sentences should be selected based on F1 to maximize differences between groups
- f0 measures beyond its mean across a sentence:
  - What role does f0 variability within a sentence play?

In conclusion, different types of acoustic variability have different influences on speech context effects
